

⊕RAPD

Right eye

Left eye

Swinging Light Test

For detecting a relative afferent pupillary defect (RAPD) i.e., Marcus Gunn Pupil

Dark.

Both pupils equally dilated in dim light

Normal pupillary response when light shone into normal eye.

Left eye constricts (direct response)

Right eye constricts (indirect/consensual response)

Light being rapidly shifted into affected eye results in **relative dilation** of both pupils. Consensual dilation response due to light moving off the normal eye overpowers the **poor constriction response** (**direct pupillary light reflex**) from the **affected (right) eye**

Light swinging back into normal eye results in further constriction of both pupils (normal pupillary response to light).
